Project lab: the briefing

4VISO

COMPLIANCE MADE SEAMLESS

What is a Risk Assessment Lane?

- A **digital representation of a transport flow** from A → B
- Consists of:
  - Nodes (locations: warehouse, airport, hub…)
  - Transport modes (air, sea, road)
- Purpose:
  - Map the full supply chain
  - Identify risks across the journey
  - Ensure compliance & quality
- *“We make the invisible supply chain visible and measurable”*

Why It Matters

- Lack of visibility = biggest risk
- Compliance is fragmented
- Certifications ≠ always validated

- Risk lane = **single source of truth**

Minimum Company Information Needed

- **Basic company info**
  - Company name
  - Location(s)
  - Contact details
  - Type (carrier, warehouse, forwarder…)
- **Operational capabilities**
  - Storage capabilities
  - Handling capabilities
  - Transport modes supported (air, road, sea)

Hard Requirements (Critical Factors)

- These are key for risk:
  - Temperature control (e.g. 2–8°C, 15–25°C) !!!!!!!
  - Dangerous goods handling
  - Perishable goods handling
  - Secure storage (high-value goods)
  - Monitoring systems (track & trace)
- These directly impact risk scoring

Certifications

We need structured certification data:

- IATA
- GDP
- ISO standards (e.g. ISO 9001, ISO 28000)
- Local compliance certifications

Important:
Not just *having* certification
But: **is it valid and verified?**

Role of Validators

Independent validators confirm:

- Certifications
- Capabilities
- Compliance

Platform logic:

- Claimed ≠ Trusted
- **Validated = trusted**

How Transport Works (Simplified Flow)

- Explain super simple:
  - Start: Origin (A)
  - End: Destination (B)
  - In between:
    - Add nodes (warehouse, hub, airport…)
- Example:
  Factory → Warehouse → Airport → Airline → Destination airport → Final delivery
- Key concept:
  - Every step = **node**
  - Nodes can be added dynamically

Nodes in the 4Viso Platform

- Per node we show:
  - Location
  - Type (warehouse, hub, airport…)
  - Transport mode:
    - Air
    - Sea
    - Road
  - Validation status
  - Certifications

UX goal:One glance = full understanding

Node-Level Settings

- Each node can have:
  - Temperature control
  - Security level
  - Handling capabilities
  - Special conditions (pharma, fragile…)

Risk Assessment Logic

Now connect everything

We evaluate risk based on:

- Missing certifications
- No validator confirmation
- No temperature control (when needed)
- Weak security measures
- Unknown capabilities

Output:

- Highlight **risky nodes**
- Highlight **weak links in the chain**

Example Risk Scenario

Make this concrete:

- Node 1: Validated + GDP → OK
- Node 2: No temperature control → ⚠️
- Node 3: No certification → ❌

👉 Result:

- Entire lane = increased risk

NTH:Package Information Impact

Type of goods:
- Pharma
- Perishable
- Dangerous goods

Packaging:
- Passive cooling
- Active cooling
- How long?

Sensitivity:
- Temperature
- Shock
- Time

👉 Risk = combination of:
lane + nodes + package

NTH: APIs & Data Integration

- To make this scalable:
  - Shipment APIs (tracking data)
  - Temperature sensor APIs (IoT)
  - Carrier APIs (status updates)
  - Customs / logistics APIs

- Examples:
  - Track & trace integrations
  - Real-time condition monitoring

- 👉 Goal:
- Automated risk insights (not manual)
